### Features

- Maximum constant output current: 750mA
- 96% efficiency @ input voltage 12V, 350mA, 3-LED
- 6~30V input voltage range
- Hysteretic PFM improves efficiency at light loading
- Settable output current
- Integrated power switch with 0.45ohm low Rds(on)
- Full protection: Thermal/Start-Up/LED Open-/Short- Circuit
- Only 4 external components required

### Product Description

The MBI6652 is a high efficiency, constant current and step-down DC/DC converter. It is designed to deliver constant current to light up high power LED with only 4 external components. With hysteretic PFM control scheme, MBI6652 improves the efficiency of light loading. The output current of MBI6652 can be programmed by an external resistor and LED dimming can be controlled via pulse width modulation (PWM) through DIM pin. In addition, the start-up function limits the inrush current while the power is switch on. The MBI6652 also features over temperature protection, LED open-circuit protection and LED short-circuit protection to protect IC from being damaged.

Additionally, to ensure the system reliability, the MBI6652 builds thermal protection (TP) function inside. This function protects IC from overheating (165°C) in various application conditions. MBI6652 provides thermal- enhanced packages as well to handle power dissipation more efficiently. MBI6652 is available in SOT-23-6Land MSOP-8L packages.

### Applications

- Signage and Decorative LED Lighting
- Automotive LED Lighting
- High Power LED Lighting
- Constant Current Source
**Typical Application Circuit**

- $V_{IN}$
- $C_{IN}$
- $C_{BP}$
- $C_{OUT}$
- $L_1$
- $D_1$
- $R_{SEN}$
- $V_{OUT}$

C\(_{IN}\): VISHAY, 293D106X9050D2TE3, D case Tantalum Capacitor
C\(_{OUT}\): VISHAY, 293D106X9050D2TE3, D case Tantalum Capacitor
C\(_{BP}\): TAIYO YUDEN, UMK212B7104MG-T, 0805 Ceramic Capacitor
L\(_1\): GANG SONG, GSDS106C2-680M
D\(_1\): ZOWIE, SSCD206
R\(_{SEN}\): VIKING, CS06FTEUR100, 1206

*To eliminate noise influence, the thermal pad is suggested to connect to GND on PCB. In addition, when a heat-conducting copper foil on PCB is soldered with thermal pad, the desired thermal conductivity will be improved.
# Maximum Ratings

Operation above the maximum ratings may cause device failure. Operation at the extended periods of the maximum ratings may reduce the device reliability.

*The PCB size is 76.2mm*114.3mm in simulation. Please refer to JEDEC JESD51.

** Operation at the maximum rating for extended periods may reduce the device reliability; therefore, the suggested junction temperature of the device is under 125°C.

Note: The performance of thermal dissipation is strongly related to the size of thermal pad, thickness and layer numbers of the PCB. The empirical thermal resistance may be different from simulative value. Users should plan for expected thermal dissipation performance by selecting package and arranging layout of the PCB to maximize the capability.
### Electrical Characteristics

Application Information

The MBI6652 is a simple and high efficient buck converter with capability to drive up to 750mA of loading. The MBI6652 adopts hysteretic PFM control scheme to regulate loading and input voltage variations. The hysteretic PFM control requires no loop compensation bringing very fast load transient response and achieving excellent efficiency at light loading.

Setting Output Current

The output current (I_{OUT}) is set by an external resistor, R_{SEN}. The relationship between I_{OUT} and R_{SEN} is as below:

\[ V_{SEN} = 0.1V; \]
\[ R_{SEN} = \frac{V_{SEN}}{I_{OUT}} = \frac{0.1V}{I_{OUT}}; \]
\[ I_{OUT} = \frac{V_{SEN}}{R_{SEN}} = \frac{0.1V}{R_{SEN}} \]

where R_{SEN} is the resistance of the external resistor connecting to SEN terminal and V_{SEN} is the voltage of external resistor. The magnitude of current (as a function of R_{SEN}) is around 700mA at 0.143Ω.

Minimum Input Voltage and Start-up Protection

The minimum input voltage is the sum of the voltage drops on R_{SEN}, R_s, DCR of L1, R_{ds(on)} of internal MOSFET and the total forward voltage of LEDs. The dynamic resistance of LED, R_s, is the inverse of the slope in linear forward voltage model for LED. This electrical characteristic can be provided by LED manufacturers. The equivalent impedance of the MBI6652 application circuit is shown in Figure 57. As the input voltage is smaller than minimum input voltage such as start-up condition, the output current will be larger than the preset output current. Thus, under this circumstance, the output current is limited to 1.15 times of preset one as shown in Figure 58.

![Figure 57. The equivalent impedance in a MBI6652 application circuit](image)

![Figure 58. The start-up waveform @ V_{IN}=12V, V_{OUT}= 10.8, R_{SEN}=0.27 Ω](image)
Dimming

The dimming of LEDs can be performed by applying PWM signals to DIM pin. A logic low (below 0.5V) at DIM will disable the internal MOSFET and shut off the current flow to the LED array. An internal pull-up circuit ensures that the MBI6652 is ON when DIM pin is unconnected. Therefore, the need for an external pull-up resistor will be eliminated. The following Figure 59 and 60 show good linearity in dimming application of MBI6652.

![Figure 59. DIM duty cycle: 1% ~ 100%](image)

![Figure 60. DIM duty cycle: 1% ~ 10%](image)

LED Open-Circuit Protection

When any LED connecting to the MBI6652 is open-circuited, the output current of MBI6652 will be turned off. The waveform is shown in Figure 61.

![Figure 61. Open-circuit protection](image)

LED Short-Circuit Protection

When any LED connecting to the MBI6652 is short-circuited, the output current of MBI6652 will still be limited to its preset value as shown in Figure 62.

![Figure 62. Short-circuit protection](image)
TP Function (Thermal Protection)

When the junction temperature exceeds the threshold, $T_x$ (165°C), TP function turns off the output current. The waveform can refer to Figure 63. The SW stops switching and the output current will be turned off. Thus, the junction temperature starts to decrease. As soon as the temperature is below 135°C, the output current will be turned on again. The switching of on-state and off-state are at a high frequency thus the blinking is imperceptible. The average output current is limited and therefore, the driver is protected from being overheated.

![Figure 63. Thermal protection](image)

Design Consideration

Switching Frequency

To achieve better output current accuracy, the switching frequency should be determined by minimum on/off time of SW waveform. For example, if the duty cycle of MBI6652 is larger than 0.5, then the switching frequency should be determined by the minimum off time, and vice versa. Thus the switching frequency of MBI6652 is:

$$f_{SW} = \frac{1}{T_S} = \frac{1}{T_{OFF,\text{min}}}, \text{ when the duty cycle is larger than 0.5}$$

or

$$f_{SW} = \frac{1}{T_S} = \frac{1}{T_{ON,\text{min}}} \frac{D}{D}, \text{ when the duty cycle is smaller than 0.5.}$$

The switching frequency is related to efficiency (better at low frequency), the size/cost of components (smaller/cheaper at high frequency), and the amplitude of output ripple voltage and current (smaller at high frequency). The slower switching frequency comes from the large value of inductor. In many applications, the sensitivity of EMI limits the switching frequency of MBI6652. The switching frequency can be ranged from 40kHz to 1.4MHz.

LED Ripple Current

A LED constant current driver, such as MBI6652, is designed to control the current through the cascaded LED, instead of the voltage across it. Higher LED ripple current allows the use of smaller inductance, smaller output capacitance and even without an output capacitor. The advantages of higher LED ripple current are to minimize PCB size and reduce cost because of no output capacitor. Lower LED ripple current requires larger inductance, and output capacitor. The advantages of lower LED ripple current are to extend LED life time and to reduce heating of LED. The recommended ripple current is from 5% to 20% of normal LED current.
Component Selection

Inductor Selection
The inductance is determined by two factors: the switching frequency and the inductor ripple current. The calculation of the inductance, $L_1$, can be described as

$$L_1 > (V_{IN} - V_{OUT} - V_{SEN} - (R_{ds(on)} \times I_{OUT})) \times \frac{D}{f_{SW} \times \Delta I_L}$$

where

- $R_{ds(on)}$ is the on-resistance of internal MOSFET of the MBI6652. The typical is $0.45\ \Omega$ at $12\ V_{IN}$.
- $D$ is the duty cycle of the MBI6652, $D=V_{OUT}/V_{IN}$.
- $f_{SW}$ is the switching frequency of the MBI6652.
- $\Delta I_L$ is the ripple current of inductor, $\Delta I_L=(1.15 \times I_{OUT})-(0.85 \times I_{OUT})=0.3 \times I_{OUT}$.

When selecting an inductor, not only the inductance but also the saturation current that should be considered as the factors to affect the performance of module. In general, it is recommended to choose an inductor with 1.5 times of LED current as the saturation current. Also, the larger inductance gains the better line/load regulation. However, the inductance and saturation current become a trade-off at the same inductor size. An inductor with shield is recommended to reduce the EMI interference, however, this is another trade-off with heat dissipation.

Schottky Diode Selection
The MBI6652 needs a flywheel diode, $D_1$, to carry the inductor current when the MOSFET is off. The recommended flywheel diode is schottky diode with low forward voltage for better efficiency. Two factors determine the selection of schottky diode. One is the maximum reverse voltage. The recommended rated voltage of the reverse voltage is at least 1.5 times of input voltage. The other is the maximum forward current, which works when the MOSFET is off. And the recommended forward current is 1.5 times of output current. Users should carefully choose an appropriate schottky diode which can perform low leakage current at high temperature.
Input Capacitor Selection

The input capacitor, $C_{\text{IN}}$, can supply pulses of current for the MBI6652 when the MOSFET is ON. And $C_{\text{IN}}$ is charged by input voltage when the MOSFET is OFF. As the input voltage is lower than the tolerable input voltage, the internal MOSFET of the MBI6652 remains constantly ON, and the LED current is limited to 1.15 times of normal current. The recommended value of input capacitor is 10uF to stabilize the lighting system. The rated voltage of input capacitor should be at least 1.5 times of input voltage. Compromising availability and cost, an electrolytic capacitor is more frequently used.

For system stability, placing the $C_{\text{IN}}$ to the VIN pin of MBI6651 as close as possible is recommended. However, the actual PCB layout and size might limit this applicability. Therefore, it is suggested to position a tiny bypass capacitor, $C_{\text{BP}}$, to the VIN and GND pins of MBI6651 as close as possible, and parallel with the $C_{\text{IN}}$ to enhance power noise injection capability. The recommend capacitance range is from 0.1uF to 1uF, and ceramic type is a good option.

The rated voltage, capacitance, and the maximum ripple current are the major concerns when selecting an input capacitor. It is important to carefully select the specification of maximum ripple current of input capacitor when in application. Both the IC and the capacitor may be damaged, if the rated ripple current of the selected capacitor is insufficient. In general, the ripple current is related to the inductor ripple current. The maximum ripple current specification should be larger than 1.3 times of the inductor ripple current.

A tantalum or ceramic capacitor can also be used as an input capacitor. The rated voltage of input capacitor should be at least 1.5 times of input voltage. A tantalum or ceramic capacitor can be used as an input capacitor. The advantages of tantalum capacitor are high capacitance and low ESR. The advantages of ceramic capacitor are high frequency characteristic, small size and low cost. Due to low ESR characteristic of ceramic capacitor, please do not use hot plugging. Users can choose an appropriate one for their applications.

Output Capacitor Selection (Optional)

A capacitor paralleled with cascaded LED can reduce the LED ripple current and allow smaller inductance.
PCB Layout Consideration
To enhance the efficiency and stabilize the system, careful considerations of PCB layout is important. There are several factors should be considered.

1. A complete ground area is helpful to eliminate the switching noise.
2. Keep the IC’s GND pin and the ground leads of input and output filter capacitors less than 5mm.
3. To maximize output power efficiency and minimize output ripple voltage, use a ground plane and solder the IC’s GND pin directly to the ground plane.
4. To stabilize the system, the heat sink of the MBI6652 is recommended to connect to ground plane directly.
5. Enhance the heat dissipation, the area of ground plane, which IC’s heat sink is soldered on, should be as large as possible.
6. The input capacitor should be placed to IC’s VIN pin as close as possible.
7. To avoid the parasitic effect of trace, the RSEN should be placed to IC’s VIN and SEN pins as close as possible.
8. The area, which is composed of IC’s SW pin, schottky diode and inductor, should be wide and short.
9. The path, which flows large current, should be wide and short to eliminate the parasite element.
10. When SW is ON/OFF, the direction of power loop should keep the same way to enhance the efficiency. The sketch is shown as Figure 64.
11. To avoid unexpected damage or malfunction to the driver board, users should pay attention to the quality of soldering in the PCB by checking if cold welding or cold joint happens between the pins of IC and the PCB.

Package Power Dissipation (PD)

The maximum power dissipation, $P_D(\text{max})=(T_J-T_a)/R_{th(j-a)}$, decreases as the ambient temperature increases.

![MBI6652 Maximum Power Dissipation at Various Ambient Temperature](image)

- GST Type: $R_{th}=244^\circ C/W$
- GMS Type: $R_{th}=37.53^\circ C/W$

Safe Operation Area
Soldering Process of “Pb-free” Package Plating*

Macroblock has defined "Pb-Free" to mean semiconductor products that are compatible with the current RoHS requirements and selected 100% pure tin (Sn) to provide forward and backward compatibility with both the current industry-standard SnPb-based soldering processes and higher-temperature Pb-free processes. Pure tin is widely accepted by customers and suppliers of electronic devices in Europe, Asia and the US as the lead-free surface finish of choice to replace tin-lead. Also, it adopts tin/lead (SnPb) solder paste, and please refer to the JEDEC J-STD-020C for the temperature of solder bath. However, in the whole Pb-free soldering processes and materials, 100% pure tin (Sn) will all require from 245 °C to 260°C for proper soldering on boards, referring to JEDEC J-STD-020C as shown below.
